### Abstract

Bariatric surgery is the only proven effective long term weight loss therapy for severe obesity and related co-morbidities. However, overall interdisciplinary support after bariatric surgery is extremely important in achieving long term success and preventing possible serious clinical disorders as well. Authors present algorithms for post-surgical patient follow-up, timings, meal progression and diet composition as well as relevant clinical, lab and nutritional checks linked to particular bariatric procedures. Recommended dosages of proteins, micronutrient supplementation after operations limiting absorption of nutrients, stomach capacity, or combined ones according contemporary guidelines are summarized. Management of post-bariatric patient in pre-gestational period and during pregnancy is also discussed.

### Abstrakt

Bariatrická chirurgia je jedinou dokázanou účinnou dlhodobou liečbou na redukcii telesnej hmotnosti pri ťažkej obezite a s ňou súvisiacich komorbiditách. Mimoriadne dôležitou pre pre dosiahnutie dlhodobého úspechu, ale aj pre prevenciu možných vážnych klinických udalostí je celková interdisciplinárna podpora po bariatrickom chirurgickom zákroku. Autori v práci prezentujú algoritmy zamerané na sledovanie pacientov po bariatrickej chirurgii, načasovanie, progresiu jedla, zloženie stravy, ako aj príslušné klinické, laboratórne a nutričné kontroly spojené s konkrétnymi bariatrickými postupmi. Sumarizujú odporúčané dávky bielkovín, suplementáciu mikronutrientov po operáciách obmedzujúcich absorpciu živín, kapacitu žalúdka alebo po kombinovaných operáciách v súlade so súčasnými odporúčaniami. Diskutujú manažment pacientiek po bariatrickej chirurgii v predgestačnom období a počas tehotenstva.

## Introduction

Bariatric surgery has become highly popular during the last 25 years. While Buchwald and Oien [1] have calculated that more than 344 thousand bariatric surgery operations were performed in 2008 worldwide, the number of procedures has risen to approximately 500 thousands in 2013 [2]. This is the result of obesity epidemic, increased proportion of severely obese and especially the fact, that bariatric and metabolic surgery is safe and highly effective therapy of clinically severe obesity and its metabolic comorbidities in long run.

Bariatric procedures can be categorised as predominantly restricting stomach capacity (restrictive), such as

laparoscopic adjustable gastric banding (LAGB), laparoscopic sleeve gastrectomy (LSG) and greater curvature plication (GCP), combined, such as the most prevalent bariatric procedure in US, Roux-en Y gastric bypass (RYGB), and malabsorptive thus limiting intestinal absorption, such as biliopancreatic diversion (BPD) or biliopancreatic diversion with duodenal switch (BPD DS). Effect on weight loss is the greatest after malabsorptive procedures, followed by combined and finally by restrictive operations, as has been shown from several meta-analyses, i.e. by Buchwald and co-workers [3]. Inversely proportions to weight loss effectiveness, in general purely restrictive procedures lead to fewer serious

adverse effects and are associated with lower risk of potential nutritional derangements postoperatively. Restrictive procedures act mostly through reducing capacity of stomach and as a result limit patient in food portion size. Some procedures, such as LSG, RYGB and potentially GCP decrease secretion of hydrochloric acid, thus compromise the oxidation of ferrous substances to ferritic ones. Depressed secretion of intrinsic factor of vitamin B12, may lead to lowered absorption of this vitamin in ileum.

RYGB, BPD and BPD-DS bypass duodenum, proximal jejunum and in BPD and BPD-DS even larger segments of proximal and mid part of small intestine. Duodenum and proximal jejunum play important role in the absorption of calcium, iron, zinc, magnesium, and copper; due to after RYGB, BPD and BPD-DS there is a limited absorption of these minerals. Moreover as biliopancreatic juices are diverted to more distal part of the small intestine (depending on the type of procedure), thereby causing maldigestion of macronutrients and limiting absorption of glucose and water soluble vitamins in the case of RYGP or in the case of BPD also the absorption of fat, vitamins A, D, E, K, vitamin B 12 and bile acids reabsorption. There is also higher risk of protein malnutrition especially after procedures that leave relatively short common limb.

Several studies focused on the risk of possible nutrient deficiencies, namely after RYGB and BPD were published [4,5]. However results of these studies differ significantly, depending on bariatric procedures modification such as the length of the alimentary limb in RYGB or the length of the common limb in BPD, the time of study after operation, algorithm of postoperative supplementation, weight loss achievement, food intolerances, diet composition, nutritional state of patients prior operation, etc. [6,7].

Surgical alterations in gastrointestinal anatomy may lead to the development of gastrointestinal maldigestive symptoms like vomiting, more prevalent after restrictive procedures, an early and late dumping syndrome after procedures bypassing pylorus, the state of hyperinsulinemic hypoglycaemia, lactose intolerance emerging in some patients after RYGB and BPD or steatorrhea, bloating and foul smelling associated mostly with BPD. These symptoms need nutritional management and have a tendency to disappear over time.

Bariatric surgery procedures improve metabolism and increase satiety through several pathways [8,9,10,11]. One of the possible mechanisms of action may be based on modulating nutrient-neuro-endocrine signalling of

gastrointestinal tract to peripheral tissues by enhancing insulin sensitivity and improving beta cells function mediated through incretin changes after bariatric procedures. Changed gastrointestinal signals after bariatric surgery may influence not only satiety, but also, in the integration with other peripheral signals, may arrange a new set-up point for body weight, metabolism and nutrition intake control by brain.

Taking into account all these facts postsurgical patients need comprehensive dietary management in both short and long-term postoperative period (tab. 1).

The early post-surgery diet should be focused in general on sufficient hydration, with fluid intake over 1.5 l/ per day, maintaining a urine output of more than 30mL/h. However on the other hand it's also important to avoid volume overload by drinking smaller volumes rather frequently, and meet protein needs depending on type of bariatric procedure of minimally 60 g/day [12]. Progression of diet consistency from clear liquids to full liquids, than from pureed to soft solid and to solid diet is also very important, especially after restrictive operations. Patients should be instructed about their eating manner: from sipping to eating multiple small meals each day, chewing thoroughly and waiting at least 30 minutes between separately consuming liquids and solids [13,14,15].

During the initial clear liquids phase usually introduced after restrictive procedures on postoperative day 1 – 2 or even later on (post-op days 2–3) following combined (hybrid) or malabsorptive procedures, patients start on sips 30–60 ml per hour of no calories, no sugar, no caffeine, no carbonated water and salty fluids (crystal light).

Next, so called full liquid phase is composed of liquid or semiliquid consistency of food and sufficient amount of protein in the form of protein-rich liquids, as chicken broth, skimmed or not fat milk or soymilk, sugar free gelatine or protein shakes (20 g of protein/serving). Patient should be instructed to sip 2.5 l of these liquids with content more than 60 g protein daily.

Pureed diet is based on soft, moist, diced, ground or pureed protein sources as tolerated, given 4–5 times daily in different volumes depending on the type of the procedure, completed by 2 l of liquids daily. Pureed chicken, turkey, tuna, but also peeled pureed fruit and vegetables, pudding, oatmeal, yogurt are gradually added into the diet with the aim to reintroduce foods from all different food groups. During pureed phase many bariatric centres recommend initiation of usage of chewable multiple vitamin and minerals supplements.

**Tab. 1 | Goals of dietary management in both short and long-term postoperative period**

immediately after procedure		from long perspective
sufficient hydration		the achievement and maintenance of the required weight loss and metabolic improvement
progressive adaptation of changed GIT to the required diet		the prevention of nutritional derangements
nutritional support for	rapid recovery from operation	the early diagnosis and treatment of nutritional deficiencies
	metabolic improvement	
	weight loss initiation	

When soft solid diet is advanced special attention must be given to mindful eating and chewing. This apply especially after gastric band procedures, where stomach restriction together with presence of relatively narrow channel connecting proximal and distal parts of the stomach may increase risk of obstruction in case food is not thoroughly chewed. Soft solid diet should be focused on soft consistency and on variety of foods from each food category, however patients are instructed to avoid food sources of carbohydrate such as rice, pasta, bread, until consuming 60 g of protein, completed by peeled soft fruit and well-cooked vegetables. During this phase foods should be chopped or diced, encompassing low content of sugar and fat, given in 3–6 small meals, separately from liquids. Recommended daily dose of protein differ according to procedure, with the daily amount of 60 g or more for those with purely restrictive or RYGB or should be in the range of 80 to 120 g for patients with BPD (DS) [12].

The timing of previously described gradual reintroduction of diet generally differs according to procedures (tab. 2), but also according to bariatric centers. There is no set standard but the adjustments of diet protocol should be made according to each patient's individual needs.

A healthy balanced diet for early postsurgical bariatric patients must be energy limited, based on protein, calcium, and iron sources, completed by vegetables and fruit and by limiting the amount of carbohydrate sources. There are foods, which generally should be avoided because of free or soft calories and the risk of stoma obstruction as snack foods (French fries, potato chips, nuts), high-calorie sweets, carbonated sweetened or alcoholic beverages, sweetened water, fibrous vegetables (dried beans, peas, celery and cabbage).

The late post-surgery diet and minimal requirements for nutritional management are defined i.e. in the Interdisciplinary European guidelines on surgery of severe obesity (IEGSSO), published in 2008 by the Bariatric scientific collaborative group [16] and in the Interdisciplinary European guidelines on bariatric and metabolic surgery, published in 2014 by International Federation for the Surgery of Obesity – European Chapter (IFSO-EC); European Association for the Study of Obesity (EASO); and European Association for the Study of Obesity

Management Task Force (EASO OMTF) [17]. According to these guidelines all patients after bariatric procedures require regular lifelong qualified surveillance. The minimal Requirements for Follow-up after Bariatric Surgery recommend: a check-up after 1 month after initial surgery, a subsequent minimal follow-up every 3 months during the first postoperative year, than every 6 months during the second year and annually thereafter. In the case of LAGB band adjustments should be performed according to the individual patient weight loss and the type of the implant, during the second postoperative year the minimal requirement for follow up is only one check-up. Follow-up should be carried out by the interdisciplinary team and should include dietary change/behavioural modification/physical activity interventions and encouragement as well as pharmacology support and surgical revision if appropriate [17]. As of nutritional requirements follow-up close weight loss control is recommended at each follow-up visit as well as check of nutritional value of ingested food and supplements (diet composition from diet records, control of food tolerance and supplements usage), comprehensive management of maldigestive symptoms, and monitoring of laboratory values and an immediate correction of nutritional and metabolic changes is desirable (tab. 2).

According to the Swedish Obese Subject Study published data [18], postoperative weight development can be divided into 3 parts: weight loss phase where the vast of majority of weight loss is accomplished in about 12 to 18 months postoperatively, followed by approximately 5 year of weight regain phase, in which about one –tenth to one-third of the initial weight loss is regained and the weight stability phase lasting for 6–15 years, during which the study was conducted.

Different weight loss outcomes according to the procedure performed as well as patient related variability in weight loss can be expected. However, in case of grossly inadequate (low) weight loss it is useful to seek for technical-surgical failure, and/or look for potential presence of maladaptive eating behaviour, altered and poor compliance with dietary recommendations and behavioural changes, non-compliance with dietary plan or presence of concomitant psychological complications, which need to be treated by multidisciplinary team of professionals.

**Tab. 2 | The minimal requirement on laboratory test after bariatric operations**

procedure	laboratory tests to evaluate the metabolic and nutritional status	minimal frequency
LAGB	fasting glucose (+HbA1c in diabetics), liver function tests, renal function, vitamin B <sub>1</sub> , B <sub>9</sub> (folates), B <sub>12</sub> , 25(OH) vitamin D3, ferritin, parathormone, albumin, Hb, Ca <sup>2+</sup> , checks, as well as basic blood cells, haemoglobin and electrolytes tests	annually
GCP		
SG		
RYGB

	complete blood cell count, complete blood electrolytes tests	
	minimal nutritional parameters should be vitamin B <sub>12</sub> , 25(OH) vitamin D3, parathormone, <b>bone alkaline phosphatase</b> , ferritin, Ca, <b>pre-albumin</b> , albumin, <b>transferrin</b> , creatinine, <b>prothrombin time (PPT)</b> , etc.	
	urine examination	

Basic nutritional recommendations according the Interdisciplinary European guidelines on surgery of severe obesity (IEGSSO).

Following restrictive (food limitation) operations metabolic and nutritional status of patients should be regularly monitored to prevent nutrients deficiency and allow appropriate supplementation. It is essential that the patients are provided with continuous educational nutrition support which should decrease the risk of vomiting. It is important to turn patient's attention to early signs of fullness, to teach them how to eat slowly, chew food well and drink plenty of non-caloric, non-carbonated fluids, separately from solid foods. Portion size should be reduced according to the type of food limitation operation performed, and in the case of further insufficient weight loss in patients with gastric band an adjustment of the band may be considered.

After combined bariatric procedures, oral vitamin and mineral supplements should be routinely prescribed. Laboratory tests should be carried out at least annually to monitor the patients' nutritional status and deficiencies should be corrected usually by parenteral supplementation. Patients should be educated as to how to manage possible lactose intolerance, dumping syndrome or hyperinsulinemic hypoglycaemia. In case of secondary lactose intolerance, patients displaying a wide range of gut and systemic symptoms, including bloating, gut pain, diarrhoea or constipation, severe headaches, severe fatigue. Because lactose intolerance has tendency to disappear with time after operation symptoms may be temporarily ameliorated through decrease intake of lactose up to 12 g daily according to patient individual tolerance [19]. Lactose may be completed with oral lactase, and probiotics administration. Dumping syndrome may produce symptoms such as postprandial sensation of abdominal pain and distension, with vasomotor changes including flushing, palpitations, and dizziness [19], vomiting, and/or diarrhoea and hypoglycaemia. These symptoms can usually be prevented by avoiding simple carbohydrates and by including proteins to each meal or snack, eating and drinking slowly, chewing foods thoroughly, drinking liquids between meals and before, however drinking together with meals should be avoided. Reclining position for 30 minutes after meals may help to reduce the undesirable symptoms. Dumping syndrome usually spontaneously disappears after 12–18 months after operation. Some patients after RYGB experience hyperinsulinemic hypoglycaemia [21], which may be resistant to nutritional interventions such as avoiding simple sugars, or pharmacological treatment by verapamil or acarbose, the partial pancreatectomy in serious states may be necessary [22].

Recommendations for minimal follow up after operations limiting absorption of nutrients are slightly more complex because of higher risks of malnutrition. Thus laboratory tests should be performed 1, 4, 12 months after BPD or BPD-DS and then at least annually, with the aim to early diagnose and treat potential nutritional

deficiency [17]. Education of patients should be targeted to their compliance with lifelong nutrient supplementation and regular follow ups. Their diet should contain sufficient amount of protein, and should be low fat. Proton pump inhibitors may be useful in case of presence of hyperacidity symptoms and in case of bloating or foul smelling stools oral treatment with neomycin or metronidazole or pancreatic enzymes is recommended.

For all bariatric surgery patients is recommended to use daily vitamin and micronutrient supplements to compensate for their possible reduced intake and absorption. A routine supplementation after SG, RYGB, BPD and BPD DS consists of one or two multivitamin with minerals tablets. It's recommended to supplement separately calcium in a daily dose of 1g preferably in the form of citrate, completed by vitamin D 2000–4000 IU daily [23]. However during all check out is necessary to actively seek out possible macro- and micronutrients deficiencies, validate clinical symptoms by laboratory tests and correct them by appropriate nutritional management. Except protein malnutrition, occurring especially after BPD (DS) and RYGB, the most prevalent deficiencies are: iron, calcium, vitamin D, vitamin B12, folate, vitamin B1, vitamin K, vitamin A, vitamin E, zinc, copper.

Iron deficiency should be treated by daily oral dose of 60 – 180 mg of elemental iron in the form of fumarate. Cobalamin – vitamin B12 may be substituted orally in dose 100–1000 µg daily, however probably the best way of administration of vitamin B12 is intramuscular injection 1000 µg monthly or 3000 µg every six months [12,23]. Patients with preoperative or postoperative already developed biochemical deficiency need even higher doses: vitamin A (10000–20 000 IU/d), vitamin D (400–50000 IU/d), vitamin K (1 mg/d), folate (400–1000 µg), thiamine (initially 500 mg daily intravenously, than stepwise reduce to 100 mg orally [12,23]. However individual adjustment of supplementation according to laboratory values is imperative to prevent not only deficiencies but also the adverse effect from overdoses of nutrients [24]. Restrictions for simultaneous administration of certain supplements in order to prevent undesirable interactions; for example iron – calcium, iron- zinc, zinc – copper should be respected.

The most prevalent nutritional dysbalances and disorders after bariatric surgery are anemia, caused by iron, vitamin B12, or folate deficiencies; metabolic bone disease which needs the care of a specialist and in some cases treatment with mega doses of vitamin D [13,25,26]. Peripheral neuropathy caused by thiamine and vitamin B12 is also a relatively frequent problem. Protein malnutrition is not diagnosed that frequently after bariatric surgery, however attention in this regards should be paid not only to post BPD (DS) patients, but to post RYGB patients as well [27].

Relatively rare nutritional deficiencies after bariatric surgery usually presented in literature as case reports are listed in [tab. 3](#).

Special attention is required in patients with protracted vomiting after any bariatric procedure. They should be screened for thiamine deficiency and for mineral derangement. Which is the best diagnosed by the determination of the effect of thiamin pyrophosphate in erythrocyte thiamin transketolase, where low erythrocyte thiamin transketolase activity with greater than 16% response to thiamin pyrophosphate is diagnostic of thiamine deficiency [28]. In patients displaying neurologic symptoms suggestive of thiamine deficiency, ophthalmoplegia, ataxia, and encephalopathy with unexpected mental status changes, weakness, dizziness, blurred vision, confusion, disorientation, (Wernicke encephalopathy), an aggressive parenteral supplementation of thiamine 500 mg/d should be started immediately after blood samples have been drawn.

Specific care should be provided to postbariatric women in the child bearing period. Women are generally recommended to delay pregnancy for at least 12–18 months after surgery. During this pre-gestational period it is important to correct nutritional deficiencies and supplement folic acid in a daily dose of 1 mg. A daily intake of higher than 1600 kcal is recommended during pregnancy to achieve moderate weight gain of 6 to 9 kg or 7 to 11.5 kg in case of obesity or overweight respectively [29]. Monitoring of protein, iron, calcium, vitamin D, vitamin A, and other nutrients in the diet and according to plasma nutritional laboratory levels is important.

### Conclusion

Apart from limited absorption of nutrients, food restriction and change of satiety, which are considered as part of treatment strategy, beside food intolerance, which should be under the control of dieticians, and exceptionally surgical and metabolic complications, the risk of nutritional derangement rises with the degree of weight loss and with patient non-compliance to diet, supplements and follow ups. The highest risk factor is the lack of patient adherence to both supplement recommendation and follow ups. Poor compliance to the diet recommendation is modifiable by repeated patient centred education by a multidisciplinary team. This team basically consists of a medical physician, surgeon, gastroenterologist or another specialist, dieticians and psychologist. It is well known and evidence based that bariatric surgery is associated with: long term weight

loss, the improvement and disappearance of metabolic co-morbidities, and decreased overall mortality. However outcomes of these procedures, and especially prevention and early treatment of potential nutritional deficiencies with potential serious health effect, depend not only on the skills of surgeons, and type of bariatric procedure, but as well on multidisciplinary support and patient-centred education prior to and after surgery, from short and long term follow ups, where the nutritionists and dieticians play an important role.
